

## Comparative evaluation of information dissemination methods for effective and efficient information sharing in wireless sensor networks

Tomoyuki Tanabe, Naoki Wakamiya and Masayuki Murata  
Osaka University, Japan

### Research background

- Wireless sensor networks (WSNs)
  - Consist of a large number of small nodes with sensing, computation, and wireless communication capabilities
- When multiple applications are running on single WSN sharing nodes and devices, nodes exchange messages with each other in each overlay network
  - It is waste to send same message in different overlay networks
  - As the number of applications increases, concurrent multiple overlays dissipate energy and bandwidth

➡ It is more energy and bandwidth efficient to share all information among all nodes through all-to-all dissemination

The diagram shows two network states. On the left, 'share information among a part of nodes through an overlay network' shows multiple overlapping layers of nodes (APP 1, APP 2, ..., APP N) with communication paths only within each layer. On the right, 'share information among all nodes through all-to-all communication' shows a single layer of nodes with communication paths between all nodes in the network. A green arrow points from the left state to the right state.

### Purpose of our research

- There have been many proposals for efficient information dissemination in WSNs
  - Characteristics of information dissemination methods differ from each other
  - Their performance depends on conditions such as the size of region and the node density
- The performance of methods is evaluated under a specific condition in preceding literatures and we cannot directly compare them
- We need to carefully select a method fulfilling requirements of desired functions under the expected operational condition
  - Ex. the number of nodes, the node density

We conduct comprehensive evaluation of information dissemination methods to clarify their comparative characteristics and the range of application

2012/11/6 APSITT2012 3

### Procedure of our research

- Classify existing information dissemination methods
  - Topology independent methods
    - flooding, gossiping and publish/subscribe
  - Topology dependent methods
    - ring, tree and cluster
- Evaluate these methods from viewpoint of the scalability by changing the size of observation region and the node density
  - the ratio of receiving nodes and the ratio of active time

2012/11/6 APSITT2012 4

### Flooding method

- Overview
  - When a node receives data, it broadcasts the receiving data to all neighbors
- Simple and easy to implement
- Waste of bandwidth
- Low delivery ratio in a high density network

A neighbor receiving the data message for the first time forwards the message to all of its neighbors

The diagram shows a network of nodes. One node is highlighted in yellow, labeled 'Sending data'. Blue arrows point from this node to all its immediate neighbors. A legend at the bottom indicates: white circle for 'Node', blue circle for 'Received node', and yellow circle for 'Sending data'.

2012/11/6 APSITT2012 5

### Gossiping method

- Overview
  - When a node receives data, it forwards the receiving data to all neighbors with probability  $p$  ( $0 < p < 1$ )
- Smaller number of transmission than the flooding method
- Difficult to set the optimal probability  $p$

A neighbor receiving the data message for the first time forwards the message with  $p$  to all of its neighbors

The diagram shows a network of nodes. One node is highlighted in yellow, labeled 'Sending node'. Blue arrows point from this node to its neighbors, but only a subset of these arrows are solid, representing the probability  $p$  of forwarding the message. A legend at the bottom indicates: white circle for 'Node', blue circle for 'Received node', and yellow circle for 'Sending node'.

2012/11/6 APSITT2012 6

### Publish/Subscribe method

- Overview
  - When a node receives data, it checks whether any neighbors have not received the data
    - Metadata: a small message which contains the information about the data to send
    - Request: forwarding request
    - Data: data message
- Low energy consumption
- × Long time for dissemination

The sender sends the data message to the requesting node

○ Node      ● Received node  
● Sending node   ● Waiting node

2012/11/6      APSITT2012

### Ring method

- Overview
  - When a node receives data, it sends the receiving data along the virtual ring topology
- Low congestion
- Low energy consumption
- × Long delay for dissemination

A node receiving the data message forwards it to the neighbor on the other side

○ Node      ● Received node  
● Sending node

2012/11/6      APSITT2012      8

### Tree method

- Overview
  - When a node receives data, it sends the receiving data to the root node of the tree
  - When the root node receives data messages, it broadcasts them to all nodes
- Low energy consumption
- Efficient in the high density network
- × The performance depends on the topology
- × High load around a root node

The root node aggregates all data messages and broadcasts them to all nodes

○ Node      ● Received node  
● Sending node   ● Root node

2012/11/6      APSITT2012      9

### Cluster method

- Overview
  - Cluster head aggregates the data messages which its cluster members receive
  - Cluster head broadcasts the aggregated data to neighbors
- Low energy consumption
- Efficient in the high density network
- × The performance depends on the structure of clusters

The border node sends the data message to another cluster head members

○ Node      ● Received node  
● Sending node   ● Cluster head

2012/11/6      APSITT2012      10

### Evaluation setting

- Simulator
  - Ns-2.34
- MAC protocol
  - IEEE 802.11
- Data generation model
  - Each node generates one data at random time from 0 to 1 [s]

Parameter	value
Communication range	100 [m]
Transmission speed	1 [Mbps]
Size of data message	1 [Kbyte]
Size of meta data	16 [byte]
Size of request message	1 [byte]

2012/11/6      APSITT2012      11

### Evaluation measures

- The ratio of receiving nodes
  - The average fraction of nodes which can receive data
$$D = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j=1}^n R(T(i), i, j)$$
- The ratio of active time
  - Total time when each node wakes up for sending or receiving data
$$W = \frac{1}{n^2} \sum_{i=1}^n \frac{\sum_{j=1}^n A(i, j)}{T(i)}$$

$R(t, i, j)$  : Whether node  $j$  has received data generated by node  $i$  by  $t$  [s]  
 $R(T(i), i, j) = \begin{cases} 1, & \text{if } i \neq j \text{ and received} \\ 0, & \text{if } i = j \text{ or unreceived} \end{cases}$   
 $T(i)$  : Time for dissemination data generated by node  $i$  to be completed  
 $A(i, j)$  : The sum of time spent by node  $j$  from beginning of carrier sense to completion in dissemination of data of node  $i$   
 $n$  : The number of nodes

2012/11/6      APSITT2012      12

### Changing the size of observation region

- Change the size of observation region
- an area of a block is  $40 \times 40$  [m]
  - One node is placed at a random location of each block
- The size of observation region is changed by changing blocks from  $8 \times 8$  blocks to  $30 \times 30$  blocks ( $64 \sim 900$  [nodes])

2012/11/6APSITT201213

### Simulation result:size

	Flooding	Gossiping	Pub/sub	Ring	Tree	Cluster
Small region	△	△	△	○	⊙	×
Large region	○	○	△	×	×	×

- When the size of observation region is smaller than  $800 \times 800$  [m] ( $256$  nodes), a tree method is more efficient
- For larger regions, a flooding method or a gossiping method is more efficient

2012/11/6APSITT201214

### Changing the node density

- Change the node density
- The size of the observation region is kept constant at  $480 \times 480$  [m]
- The observation area is divided into blocks
  - Only one node is placed at a random location of each block
- The number of blocks is changed from  $8 \times 8$  blocks ( $0.00028$  [node/m<sup>2</sup>]) to  $30 \times 30$  blocks ( $0.0039$  [node/m<sup>2</sup>])

2012/11/6APSITT201215

### Simulation result: density

	Flooding	Gossiping	Pub/sub	Ring	Tree	Cluster
Low density	○	○	△	×	⊙	×
High density	△	△	×	△	△	×

- A tree method is the most efficient in the low density network

2012/11/6APSITT201216

### Conclusion

- Conclusion
  - Conduct comparative evaluations of well known information dissemination methods
    - A tree method well fits to the small observation region independently from the node density
    - A flooding method can achieve the higher ratio of receiving nodes in the large observation region
- Future work
  - Consider a method which guarantees the reliable information dissemination for all-to-all communication
    - Retransmission and scheduling
